

# Assemble yourself

A printable bioinformatics boardgame

Assemble yourself is a paper-printable bioinformatics boardgame which is designed to be educational, fun and engaging. It introduces basic genetics and Next Generation Sequencing (NGS) through a puzzle-like problem.

The main idea of the game is to manually perform assembly of a genome sequence from NGS reads. The entire game is printed on paper. This includes the reads (cut out paperstrips) and a board which serves scaffold to assemble the reads and writing down the sequence. Once the reads have been assembled and a consensus sequence is found, the consensus sequence is translated into amino acid sequences in both DNA strands. The letters of the amino acid sequence contains a secret word embedded within an open reading frame. Once the player finds the secret word he wins the game.

The game is generated by a computer program and many aspects of the game can be configured prior to generation. For instance, the secret protein word can be changed and the minimal read depth at any loci can be configured.

The game can be played by a single person or run as a competition, e.g., in a class. I have experienced the latter scenario to be a lot of fun, especially when students work in small groups.

To get the most out the game, players should have been introduced to/be familiar with the central dogma of biology and concepts like DNA, base-pairing, amino acid, strand, reading frame, gene and codon before playing the game.

# Introduction to the game

Recently an interesting protein with the amino acid sequence ATNE was found in the bacteria *S. Equencia*. It is now to be determined if a homologue exists in the species *B. Ionformatica*.

To determine this a lab amplified a relevant part of the DNA of *B. Ionformatica* using PCR primers flanking the gene in *S. Equencia* which are believed to be highly conserved also in *B. Ionformatica*, although the sequence of *B. Ionformatica* is currently not known. The amplified DNA was sequenced using Ullamini LoSeq next generation sequencing technology yielding 16 reads. The quality of the reads are not perfect – read errors resulting in random read “mutations“ are expected in one out of twenty bases.

As a bioinformatician you are given the task to find out if *B. Ionformatica* has a homologue of the protein ATNE and determine how its amino acid sequence differs in *B. Ionformatica*. However, the high performance moon grid engine supercluster is currently down (as it sometimes is) and you have to do it all by hand. Fortunately, you have printed all the reads. Your task is as follows:

- Perform de-novo assembly of all the reads
- Find open reading frames that may contain a gene
- Find the amino acid sequence of any such gene to determine if it could be a homologue to ATNE
- Report your finding and claim eternal fame

But you have to hurry! Many other competing research groups have also gotten a hold of the reads and they will scoop you on this important discovery if you are not fast.

## Detailed instructions

Cut the reads with a scissor so you have them as paper strips. Place these paper strips horizontally on the board in the read alignment area so that they overlap each other, matching base by base. Above the read alignment area is a row which have six predefined nucleotides in each side (the PCR primers). Your reads should also match these. Once you have aligned all the reads, you can fill the empty cells with the consensus sequence obtained from the alignment. It is possible to map all the reads, but not all reads may not map to the same strand. If you end up with reads that do not fit anywhere, then most likely your alignment is wrong.

Once you have the entire consensus sequence you look for the hidden protein. In the three top of the board you can write down amino acids (and start and stop codons) for the forward strand corresponding to your consensus sequence. In the bottom you do the same for the reverse strand.

An open reading frame consist of a start codon, some intermediate codons and a stop codon. Identify open reading frames and translate intermediate codons using the supplied amino acid table. Find the protein that looks the most homologue.

**Winning the game:** The team that first correctly reports the amino acid sequence<sup>1</sup> of the protein homologue and also its nucleotide sequence wins the game.

**Feedback during the game:** During the game a team can hand in the IUPAC consensus codes of their alignment (see attached table). The judge of the game will then determine if the sequence is correct. Similarly you may make hand it a protein sequence and the judge will check its correctness (if correct, you win). However, this service comes at a price. The first time you ask it will cost you one of your reads. The second time it cost you two reads, the third time four reads and so on. So, use your reads wisely.

---

<sup>1</sup>Report amino acid sequence without the methionine encoded by the start codon

	G	GTA Val	GCA Ala	GAA Glu	GGAGly
	G	GTG Val	GCG Ala	GAG Glu	GGGGly

Standard genetic code. The table shows how triplets of nucleic acid bases correspond to different amino acids. Besides the codon ATG with always codes for methionine, alternatively TTG, CTG, ATT, ATC, ATA and GTG can serve as initiation codons, in which case they are translated as methionine rather than the amino acid indicated. However – in this game – we do not consider the first methionine as part of the solution amino acid sequence.

Nucleotide Code:	Base:
A	Adenine
C	Cytosine
G	Guanine
T (or U)	Thymine (or Uracil)
R	A or G
